## AM PLL Professional Medium-Wave Transmitter

These AM Transmitters operates between 540 KHz and 1800 KHz in the Medium Waveband (AM Band) and is designed to be reliable and stable.
Two units are available in 1 watt and a 4 watt output version. The 1 -watt version is capable of delivering over 1 watt of RMS power into a short length aerial. It can usually deliver 1.5 watts cleanly driven to $100 \%$ modulation. The 4 watt version can deliver in excess of the specified output. (Power drops off at lower frequencies -see spec below for details on the other versions)
The Transmitter circuit design employs a CMOS Phase Locked Loop oscillator circuit for accuracy and ease of frequency selection. A binary code is created by the 8 position DIP switch. It is also very stable and therefore does not drift off frequency. The Phase Lock circuit provides selection in either 9 KHz steps for UK/European Union or 10 KHz steps for USA. A suitable Crystal is used for either selection and is selected at time of ordering. A
rugged Power MOSFET is also used on the RF output stage, which drives the output toroid and variable tuning capacitor. High voltage rated components are used in the output section.
Audio modulation is series-derived using a pair of Darlington Power Transistors. These are in turn driven by an audio level control chip which allows the transmitter to achieve maximum modulation at all times, whatever the audio source and nominal level is, within reason. (CD player, mixer, PC etc) It also acts as an audio expander, so low audio levels are increased. Housed in a Steel box with ABS front and rear panels. Ventilation holes to improve air flow for component cooling. A fan is used on the higher 4 watt output models.

## POWER SUPPLY --- IMPORTANT --- PLEASE NOTE

Power is provided from an external plug-top power unit. A transmitter is supplied with a specific power unit, as certain components inside the transmitter are voltage sensitive and could either burn-out or cause damage if the wrong power voltage is applied. Therefore, only use the supplied power unit, otherwise damage may well occur.
It will be evident whether a wrong power unit has been used which in turn causes internal damage!!
The transmitter comes already set up for use, together with a mains power supply and wire aerial.

## Setup

1. Insert stripped end of wire into the Aerial terminal and screw into place
2. Hang aerial as vertically as possible at least 30 cm away from walls etc
3. Adjust frequency using DIP switches on the rear as per required settings.
4. Connect phono audio cable ( $L$ and $R$ ) to transmitter and audio source.
5. Connect power supply to DC socket and turn on unit from power switch
6. Adjust aerial tune knob for maximum power on output power display

## Advanced setup and troubleshooting

Internally, there are several links for adjustment to aerial matching across the frequency spectrum. These add additional capacitance at the lower end, a table shown further below explains the settings required. Remove top cover in order to gain access. Also there are several selector links, one is for tappings on the output coil (toroid) which is used for better aerial matching. At different frequencies, 2 other sets of links are used to put fixed capacitors across the tuning capacitor in order to maximise the matching, (links $X$ and $Y$ ) use the link to select a lower inductance for improved matching. A better match may be achieved by moving this link. Experimentation is required here.
A longer aerial wire can be used with the transmitter and will give a better range. Excellent results have been obtained using a single long wire of approximately 18 metres length as shown in the diagram. The aerial is essentially the length of the back garden, using
insulators that radio hams use. Roof top is the end of the wire, suspended via a tree at the other end. Also, the use of a good Earth helps with signal efficiency and distance. A copper stake in the ground is a good start. Search the Internet for further advice.
The link is located on the main circuit board by the circular toroid. There are 3 selections, 60 turns, 80 turns and 100 turns. Select ' $1-3$ ' for minimum ( 60 turns tapped) inductance, ' $2-3$ ' for mid-range inductance ( 80 turns) and NO LINK for maximum inductance ( 100 turns). The tap gives less inductance for much better match to the longer aerial. Maximise the signal level with the tuning control, whilst observing the signal level LED display. Or even better is the use of a Field Strength Meter, which are readily available on eBay. Note- if link isn't required, just leave it on any pin sideways and therefore not linked.

$X$ and $Y$ are shown in OFF position. Move link to left for connection in circuit.

Fine Tuning Capacitor

It is possible to fine-tune the operating frequency by adjusting VC1 on the main circuit board. (see pic) This adjustment is for alignment of the output frequency and is preset prior to shipping.

## Aerial Matching

## Various link options to output section

| $540-700 \mathrm{KHz}$ |  | Link Y |
| :--- | :--- | :--- |
| $700-840 \mathrm{KHz}$ | Link X |  |
| $840-1000 \mathrm{KHz}$ | Link X |  |
| $1000-1800 \mathrm{KHz}$ | No Link |  |

## Hum on audio

If you experience hum (normally most noticeable the further the receiver is away from the transmitter) then reposition transmitting antenna or receiver.
When used indoors the wiring running through the house picks up the signal causing "hum spots".
Repositioning to a 'non hum' area will cure this, or use the 'Hum Cancel' trimmer to null out the noise. This injects a very small $30 \mathrm{~Hz}-70 \mathrm{~Hz}$ signal into the audio chain. VR1 is 30 Hz fully anticlockwise, 70 Hz fully clockwise. 50 Hz is about $3 / 4$ around in clockwise position.

## Bluetooth connectivity

A Bluetooth module can be fitted at nominal extra cost. To use this, make sure that the wired (phono) cables are removed from the rear sockets, as this loads the audio signal down.
On your Bluetooth device, search for JH-BT for connection. It auto connects. Please note that without any audio signal the expander in the transmitter increases the noise from the Bluetooth module. But this soon disappears when audio is present.

Typical Aerial arrangement

Arrangement using supplied Aerial

Alternative 'long-wire' arrangement

Alternative arrangement using long-wire

## Frequency setting

## Setting frequency using dip switches

There are 2 versions, EU or USA spacing as controlled by different crystals to obtain either 9 KHz or 10 KHz channel spacing. EU channels are in Blue, USA in Red in the tables.
At the rear of the transmitter there are a set of dip switched numbered 1 to 8 .
Using the frequency table set the switches to the desired frequency.
For example, if your desired frequency is 1530 Khz ( 1700 KHz for USA crystal), look it up in the table and you will see its binary setting to the left.
As we can see the binary position is: 10101001
1530170010101001

The switch positions are up for 0 and down for 1 . So therefore, starting from the left-most switch and working our way to the right we get the following:

| Binary number | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 1 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Switch position | on | off | on | off | on | off | off | on |

It looks like this:

On the rear, the DIP switches determine the frequency.

## Binary switch positions

## Adjustment and alignment.

There is no PLL alignment setting other than a 'fine tune' trim using trimmer capacitor VC1 on the main circuit board. This is the brown component by the crystal. A jewellers screwdriver is used to adjust this. It is possible to 'zero-beat' with other stations on channel.

RF Drive.
The preset VR3, labelled DRIVE is used to adjust the signal drive to the output FET.

Observing the output signal 'Bargraph' display, adjust the potentiometer to achieve maximum signal output. Or use an oscilloscope to observe drain and gate voltages on the output FET. Adjusting this preset will help to maximise the output across the band.

## Audio Level

Adjust preset VR2 for maximum modulation, ideally using an oscilloscope for maximum (but not over) modulation depth. Without breaking carrier. (solid line at 0\%)

## Hum cancel

In an attempt to remove hum from the audio signal, if there is any, this is accomplished by adjustment of VR1. This is best done whilst operational. It introduces a low level $30-70 \mathrm{~Hz}$ signal into the drive. The idea is to cancel-out hum on the received audio signal.

Resetting the Frequency display

The Programmed Chip can get swamped with RF and may make it display incorrectly. (this is very uncommon but has been observed)
A micro switch (the black push button) is fitted to the display board to allow the display to be reset. Press the switch once to enter setup. Press through the stages, so that you select 'No PS' (does not enter 'sleep mode'), Zero (offset) press and hold until it flashes to set this and press to hold for exit to save setup.

RF level monitor
The Bargraph is a visual representation of carrier level and Modulation. The signal is detected by the mini RF sniffer aerial inside and this converts to the LED scale. The sensitivity of this is adjusted by VR4 on the front panel PCB and by moving the sniffer nearby to the RF Capacitor conductor between the main board and the front panel board.

## Aerial Matching

As described above, the desired operating frequency is adjusted to suit the aerial by using the linking contacts in the output section, plus the links for additional capacitance.
Use the LED tuning indicator for maximum output.

NB. Early circuit boards do not have the ' $X$ ' and ' $\gamma$ ' capacitor links. Instead external capacitors are fitted across the Aerial and Earth terminal block on the rear.

## Technical Specifications

## 1 Watt Unit

Size - 150 mm wide, 150 mm depth, 75 mm high
Weight. - 0.9 Kg
Power requirement - DC 12V @ 600mA max
Audio input - RCA Phono sockets, left and right audio between 75 mV and 775 mV RMS
Audio Bandwidth (+ -3dB) - 80Hz to 6 KHz
Modulation level - up to 100\%
RF Output level-1 Watt (or more depending on Aerial Match)
RF Output Capacitor - 370pF variable
RF connection - screw terminal for signal and earth connection
Display -
Signal level - 10 segment Bar-Graph multi-colour LED
Frequency - 4 7-segment LED display
Ventilation - passive convection

## 4 Watt Unit

Size - 150 mm wide, 150 mm depth, 75 mm high
Weight. - 1 Kg
Power requirement - DC 17-18 V @ 1A max
Audio input - RCA Phono sockets, left and right audio between 75 mV and 775 mV RMS
Audio Bandwidth (+ -3dB) - 80Hz to 6KHz
Modulation level - up to 100\%
RF Output level-3-5 Watts (dependant on Aerial Match)
RF Output Capacitor - 400pF variable
RF connection - screw terminal for signal and earth connection
Display -
Signal level - 10 segment Bar-Graph multi-colour LED
Frequency - 4 7-segment LED display
Ventilation - Cooling fan forced airflow
